Description			
<p>Going down a predefined hierarchy of an XML file is relatively cumbersome in the actual implementation. A GXmlNode::element() method should be implemented that takes a single string with a specific format that describes the XML access hierarchy, e.g.</p> <pre>params > param[1] > value > struct</pre> <p>will access the element</p> <pre><params> <param>One</param> <param> <value> <struct></pre>
